

Case 1: GET a Single Resource

Verify that fetching a single post returns the correct data and HTTP status.

API Endpoint

GET `https://jsonplaceholder.typicode.com/posts/1`

What You Will Learn

- HTTP GET method
- Status code 200 OK
- Response body validation (JSON keys and values)
- requests library basics

Study Plan

Step 1 — Understand the endpoint

Open your browser or Postman and call GET `/posts/1`. Look at the JSON response. Note the fields: `id`, `userId`, `title`, `body`.

Step 2 — Learn `requests.get()`

Read how to use `requests.get(url)` in Python. Understand that `response.status_code` gives you the HTTP code and `response.json()` parses the body.

Step 3 — Write your first assertion

In pytest, use `assert response.status_code == 200`. Then assert the returned `id` equals 1.

Step 4 — Validate JSON structure

Check that all expected keys exist in the response dict: `'id'`, `'userId'`, `'title'`, `'body'`. Use the `'in'` operator.

Step 5 — Run and review

Run `pytest -v` and confirm the test passes. Try changing the expected `id` to a wrong value to see a failure.

Your Task

Write a pytest test that calls GET `/posts/1` on JSONPlaceholder.

The test must verify:

1. Status code is 200
2. The returned post has `id == 1`
3. The response contains the keys: `userId`, `title`, `body`

Hint: Use `requests.get()` and `response.json()` to access the response body as a dict.
