

Case 2: GET a List of Resources

Verify that fetching all posts returns a list with the expected count and structure.

API Endpoint

GET <https://jsonplaceholder.typicode.com/posts>

What You Will Learn

- Validating list responses
- `len()` assertions
- Checking item structure inside a list
- Type checking with `isinstance()`

Study Plan

Step 1 — Call the endpoint

Run GET `/posts` in Postman or curl. Notice it returns a JSON array of 100 posts.

Step 2 — Understand list responses

`response.json()` will return a Python list. You can use `len()` to count items and index `[0]` to access the first item.

Step 3 — Assert the count

Assert that `len(posts) == 100`. This ensures all records are returned.

Step 4 — Check item structure

Assert that the first item in the list contains the keys `'id'`, `'userId'`, `'title'`, `'body'`.

Step 5 — Type validation

Use `isinstance(posts, list)` to confirm the response is actually a list, not a dict or string.

Your Task

Write a pytest test that calls GET `/posts` on JSONPlaceholder.

The test must verify:

1. Status code is 200
2. The response is a list
3. The list contains exactly 100 posts
4. The first post has the keys: `id`, `userId`, `title`, `body`

Hint: Remember: `response.json()` returns a Python list here. Use `len()` and `isinstance()`.
