

Case 3: POST — Create a New Resource

Send a new post payload and verify the server responds with the created resource.

API Endpoint

POST `https://jsonplaceholder.typicode.com/posts`

What You Will Learn

- HTTP POST method
- Sending JSON in request body
- Status code 201 Created
- Validating echoed-back fields

Study Plan

Step 1 — Understand POST

POST is used to create a resource. You send data in the request body as JSON. The server should return the created object.

Step 2 — Build your payload

Create a Python dict with keys: title, body, userId. This is your new post data.

Step 3 — Use `requests.post()`

Call `requests.post(url, json=payload)`. The `json=` parameter automatically sets Content-Type to `application/json`.

Step 4 — Assert 201 Created

A successful POST should return 201, not 200. Assert `response.status_code == 201`.

Step 5 — Verify the response body

JSONPlaceholder echoes back the fields you sent, plus assigns an 'id'. Assert that the title in the response matches what you sent.

Your Task

Write a pytest test that sends a POST request to `/posts`.

Payload: `{ title: 'My Test Post', body: 'Hello world', userId: 1 }`

The test must verify:

1. Status code is 201
2. Response body contains an 'id' field
3. The 'title' in the response matches what you sent

Hint: Use `requests.post(url, json=payload)`. Check `response.json()['id']` exists.
